

Data Exchange Formats

Data Exchange Formats

- ▶ XML

- ▶ A verbose textual representation of trees

- ▶ JSON

- ▶ JavaScript Object notation – like a Python `dict`

XML Format

people.xml:

```
1 <?xml version="1.0"?>
2
3 <people>
4   <person>
5     <firstName>Alan</firstName>
6     <lastName>Turing</lastName>
7     <professions>
8       <profession>Computer Scientist</profession>
9       <profession>Mathematician</profession>
10      <profession>Cryptographer</profession>
11    </professions>
12  </person>
13  <person>
14    <firstName>Stephen</firstName>
15    <lastName>Hawking</lastName>
16    <professions>
17      <profession>Physicist</profession>
18      <profession>Comedian</profession>
19    </professions>
20  </person>
21 </people>
```

Parsing XML with ElementTree

Use Python's built-in [ElementTree API](#).

```
1 In [17]: import xml.etree.ElementTree as ET
2
3 In [18]: root = ET.parse('people.xml')
4
5 In [21]: persons = root.findall("person")
6
7 In [24]: for person in persons:
8     ...:     print(person.find("firstName").text, end="")
9     ...:     print(person.find("lastName").text)
10    ...:     for profession in person.find("professions"):
11    ...:         print("\t", profession.text)
12    ...:
13 AlanTuring
14     Computer Scientist
15     Mathematician
16     Computer Scientist
17     Cryptographer
18 StephenHawking
19     Physicist
20     Comedian
```

JSON Format

Just like Python data structures except:

- ▶ double quotes (") for strings, no ' or tripple-quotes
- ▶ `true` and `false` booleans instead of `True` and `False`
- ▶ `null` instead of `None`

`people.xml` as JSON, modified so professions list more convenient:

```
1 {
2   "people": {
3     "person": [
4       {
5         "firstName": "Alan",
6         "lastName": "Turing",
7         "professions": ["Computer Scientist",
8                         "Mathematician", "Cryptographer"]
9       },
10      {
11        "firstName": "Stephen",
12        "lastName": "Hawking",
13        "professions": ["Physicist", "Comedian"]
14      }
15    ]
16  }
```

Reading JSON

Use Python's built-in [JSON encoder and decoder](#).

► Loading from a string:

```
1 In [2]: json.loads('{ "CS4400": ["CS1301","CS1315","CS1371"],  
2         "CS3600":["CS1332"] }')
```

```
2 Out[2]: {'CS3600': ['CS1332'], 'CS4400': ['CS1301', 'CS1315', 'CS1371']}
```

► Loading from a file (notice the file object, not just a file name):

```
1 In [8]: cat fall2017-breaks.json  
2 {  
3     "2017-09-04": "Labor Day",  
4     "2017-10-09": "Fall Student Recess",  
5     "2017-10-09": "Fall Student Recess",  
6     "2017-11-22": "Student Recess",  
7     "2017-11-23": "Thanksgiving Break",  
8     "2017-11-24": "Thanksgiving Break"  
9 }  
10  
11 In [9]: json.load(open('fall2017-breaks.json'))  
12 Out[9]:  
13 {'2017-09-04': 'Labor Day',  
14  '2017-10-09': 'Fall Student Recess',  
15  '2017-11-22': 'Student Recess',  
16  '2017-11-23': 'Thanksgiving Break',  
17  '2017-11-24': 'Thanksgiving Break'}
```

Writing JSON

► Dumping to a string

```
1 In [11]: prereqs = {'CS3600': ['CS1332'], 'CS4400': ['CS1301',  
2           'CS1315', 'CS1371']}  
3 In [12]: json.dumps(prereqs)  
4 Out[12]: '{"CS3600": ["CS1332"], "CS4400": ["CS1301", "CS1315",  
           "CS1371"]}'
```

► Dumping to a file (notice the write-mode file object):

```
1 In [14]: json.dump(prereqs, open('prereqs.json', 'wt'))  
2  
3 In [15]: cat prereqs.json  
4 {"CS3600": ["CS1332"], "CS4400": ["CS1301", "CS1315", "CS1371"]}
```
